Finding all common bases in two matroids

Main result

Given two matroids $M_1 = (E, \mathcal{B}_1)$, $M_2 = (E, \mathcal{B}_2)$, and a common base $B^1 \in \mathcal{B}_1 \cap \mathcal{B}_2$, there is an algorithm finding all common bases of them in $O(n(n^2 + t)\lambda)$ where λ is number of the bases and t is the time to make one pivot operation.

Finding all common bases in two matroids

- The algorithm use enumeration tree whose height is $|E| = n$ and the height is indexed in descending order from the root
- In the beginning, the initial comon base B^1 is placed at right most position
- n -dimentional vector $P \in \{L, R\}^n$ is used to indicate the current position
- also current branch is indicated by $f \in E$
- Each one step of algorithm, B^k goes left updating B^k to B^{k+1} if exists

Finding all common bases in two matroids

initial state:

$$B^1 = \{2, 3, 4\}$$
$$P = (RRRR), f = 1$$

Finding all common bases in two matroids

example:

when the current base $B^k = \{1, 3, 4\}$ is placed like above,
 $P = (LLRR)$ and $f = 3$

Finding all common bases in two matroids

next, we need a theorem to reduce the search space like a backtracking

Finding all common bases in two matroids

bipartite graph $G(B^k)$

Finding all common bases in two matroids

Theorem 1

There exists a common base B^{k+1} in L if and only if there exists a directed cycle C in $G(B^k)$ which contains f and consists of elements in E less than or equal to f .

Finding all common bases in two matroids

bipartite graph $G(B^k)$
when $f = i_6 \dots$

Finding all common bases in two matroids

bipartite graph $G(B^k)$
when $f = i_6 \dots$

Finding all common bases in two matroids

$$B^{k+1} = B^k \cup \{j_3, j_4\} \setminus \{i_3, i_6\} \in \mathcal{B}_1 \cap \mathcal{B}_2$$

Finding all common bases in two matroids

simple algorithm example:

$$M_1 = M_2 = (E, \mathcal{B})$$

$$E = \{1, 2, 3\}, \mathcal{B} = \{\{1, 2\}, \{2, 3\}\}$$

$$B^1 = \{2, 3\}$$

Finding all common bases in two matroids

$$B^1 = \{2, 3\}$$

$$P = (RRR)$$

$$P_1 = R \text{ then } f = 1$$

Finding all common bases in two matroids

$$B^1 = \{2, 3\}$$

$$P = (LRR)$$

$$P_2 = R \text{ then } f = 2$$

Finding all common bases in two matroids

$$B^1 = \{2, 3\}$$

$$P = (LLR)$$

$$P_3 = R \text{ then } f = 3$$

there exists an directed cycle C in bipartite graph $G(B^1)$
 \rightarrow make pivot operation along C and get new base $B^2 = \{1, 2\}$

Finding all common bases in two matroids

$$B^2 = \{1, 2\}$$

$$P = (RRL)$$

$$P_1 = R \text{ then } f = 1$$

Finding all common bases in two matroids

$$B^2 = \{1, 2\}$$

$$P = (LRL)$$

$$P_2 = R \text{ then } f = 2$$

Finding all common bases in two matroids

$$B^2 = \{1, 2\}$$

$$P = (L L L)$$

f doesn't exist

end

Finding all common bases in two matroids

algorithm “Enumerate”

input: $M_1 := (E, \mathcal{B}_1)$, $M_2 := (E, \mathcal{B}_2)$, $B^1 \in \mathcal{B}_1 \cap \mathcal{B}_2$

output: all common bases of M_1 and M_2

- 1 $k := 1$, output B^k . $P := (R, \dots, R)$. (Here, $P \in \{L, R\}^n$)
- 2 $f := \min\{j \mid P_j = R\}$
- 3 If f doesn't exist, stop. Else, create $G(B^k)$ and find directed cycle C satisfying theorem 1 with breadth first search.
- 4 If C doesn't exist, goto step 2. Else, $k := k + 1$, make pivot operation along C and obtain new B^k . $P_f := L$, $\forall j < k$; $P_j := R$, goto step 2.

Finding all common bases in two matroids

Again, $n = |E|$, $\lambda = |\mathcal{B}_1 \cap \mathcal{B}_2|$, and t is time to generate $G(B^k)$.

time complexity

We evaluate the time from obtaining B^k to obtaining B^{k+1} . Let A_{max} be the maximum number of the arc in $G(B^k)$. Then C in $G(B^k)$ satisfying Theorem 1 can be found in $O(A_{max})$ using BFS. This is iterated at most n times (until finding such C). If such C exists, then we pivot elements in B^k along C to get B^{k+1} and generate $G(B^{k+1})$. This takes $O(C_{max}t)$ where C_{max} is the length of the C .

Since we know $A_{max} \leq (\frac{n}{2})^2 \cdot 2 = \frac{n^2}{2}$ and $C_{max} \leq 2 \cdot \frac{n}{2} = n$, it takes $O(n^3 + nt)$ from B^k to B^{k+1} .

This is iterated λ times, so total time complexity is $O((n^3 + nt)\lambda)$.

(note: t depends on the input form of the matroid. for example, the matroid is given in a form of a map, $t = O(n^2)$, but matroid is given in a form of a matrix, it's more than n^2)

TODO:

- 1 learn about matroid intersection
- 2 learn how to partition a matroid into bases
- 3 tackle two different partition matroids (can be partitioned into their common bases)
- 4 generalized partition matroid of two different uniform matroids and any matroid
